

# Why Now?

- ① Industries are moving online.
- ② Automation: Factory floor → The back office.
- ③ Human-Human Negotiation is cumbersome, and inefficient.
- ④ Automated Negotiation opens new possibilities:
  - Too fast for people: Repeated smart contracts.
  - Too large for people: complete supply chains

# The Automated Negotiation Challenge

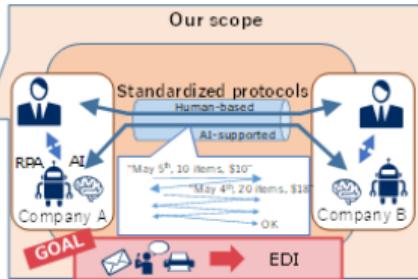

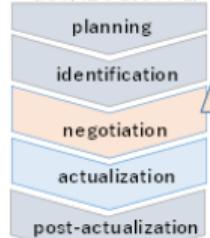

## Why is it hard?

- Mechanism Design Problem:
  - Better than haggling?
- Negotiator Design Problem:
  - Generality × Effectiveness

## Why is it interesting?

- Easy to state yet hard to solve.
- Multiple levels of abstraction and complexity.
- Several concrete open questions.
- Vibrant yet not saturated research space.

Five fundamental activities of a business transaction (ISO/IEC 15944-1)

- ② Unmediated

# Outline

1 Negotiation

2 Bargaining 101

- Abstract Problem Definition
- Bargaining Games and Solutions

# Outline

## 1 Negotiation

## 2 Bargaining 101

- Abstract Problem Definition
- Bargaining Games and Solutions

# A Joint Venture

- A factory  $F$  can manufacture a widget at cost  $C$
- A distributor  $D$  can sell a widget for revenue  $R$
- $R > C$ , so there is surplus  $R - C$  to be gained (value creation)
- Bargaining problem: how much should  $D$  pay  $F$  for the widget?  
(value division)

# Abstract Bargaining Problem

The two-person bargaining problem can be defined abstractly by

- A set  $F \subset \mathbb{R}^2$  of feasible utilities  $(u_1, u_2)$
- A disagreement point  $\phi \doteq (d_1, d_2) \in \mathbb{R}^2$ , also called the status quo.  
The value  $d_i$  is called agent  $i$ 's reservation value.

**Individual rationality** assumption: No agent will ever agree to a utility below their disagreement point

An efficient outcome is one on the **Pareto frontier**, where neither agent can be made strictly better off without making the other worse off

**Challenge:** We seek a cooperative outcome (i.e., an efficient one) in a non-cooperative game

# von Neumann-Morgenstern Utility Theorem (1944)

It is natural to express agent's preferences as comparisons: e.g., "I like apples better than bananas."

Given an agent with partial preferences with at least one strict inequality that satisfy various axioms (completeness, transitivity, continuity, and IIA),

$$\exists u : \Omega \rightarrow \mathbb{R} \text{ such that } \omega \succ \psi \text{ iff } \mathbb{E}[u(\omega)] < \mathbb{E}[u(\psi)]$$

and  $u$  is unique up to scaling.

Why is this relevant?

- Justifies focusing on bargaining assuming utility functions (hereafter, **ufuns**).
- Justifies modelling the preferences of negotiation partners (hereafter, **opponents**) via ufun.

# Outline

## 1 Negotiation

## 2 Bargaining 101

- Abstract Problem Definition
- Bargaining Games and Solutions

# Nash's Protocol (1950)

Arguably the simplest possible protocol.

- Both agents announce their demands simultaneously.
- If their demands are feasible, an agreement is reached.
- If not, the outcome is the disagreement point.

In the joint venture game (because there are now rules), we might define the agents' demands to be feasible iff the price announced by the distributor is at least the price announced by the manufacturer.

There are many possible equilibria in bargaining problems.

In the joint venture game, any price at which a trade transpires is an equilibrium.

Nash sought a theory of bargaining which would characterize a unique outcome of a negotiation.

# Nash's Demand Game (1950)

The Nash demand game:

- Two agents are offered the chance to split a dollar.
- They both announce a number in  $[0, 1]$  simultaneously.
- If the sum of the two numbers does not exceed 1, they each win what they demanded.
- Otherwise, they win nothing.

There are again many possible equilibria in the Nash demand game.

Define a player  $i$ 's surplus as the difference between the value of an agreement and its reservation value.

Nash's bargaining solution is the point at which the product of each agent's surplus is maximized:

$$\arg \max_{\omega} (u_1(\omega) - u_1(\phi))(u_2(\omega) - u_2(\phi))$$

This is the unique point that satisfies several natural axioms: efficiency, symmetry, invariance, and IIA.

# Some Automated Negotiation Platforms

## Genius<sup>1</sup>

a Java-based negotiation platform to develop general negotiating agents and create negotiation scenarios.

**GENIUS** General Environment for Negotiation with Intelligent multi-purpose Usage Simulation.

## GeniusWeb

A distributed platform for automated negotiation on the internet

## NegMAS<sup>2</sup>

a Python-based negotiation platform for developing autonomous negotiation agents embedded in simulation environments.

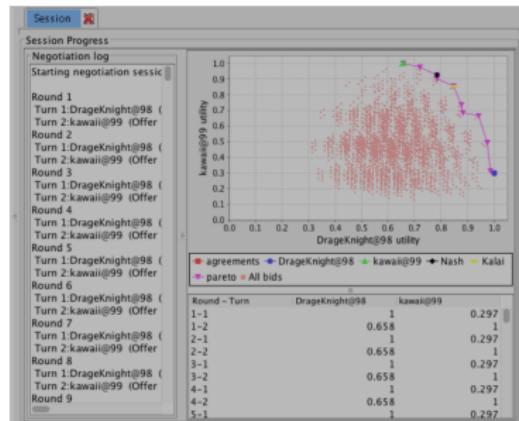

# GENIUS

## Genius<sup>3</sup>

- Originally Developed by University of Delft and University of Bar Ilan. Currently maintained by a consortium of researchers.
- Since 2008 and used in all ANAC competitions
- The defacto-standard.
- Java-based <sup>4</sup>.
- Has a GUI for running negotiations and tournaments.
- Includes SOTA agents from ANAC competitions since 2010.

# GENIUS

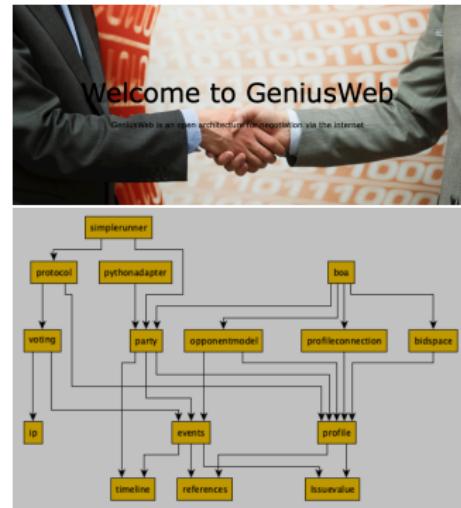

>>> General Environment for Negotiation with Intelligent multi-purpose Usage Simulation.

# GeniusWeb

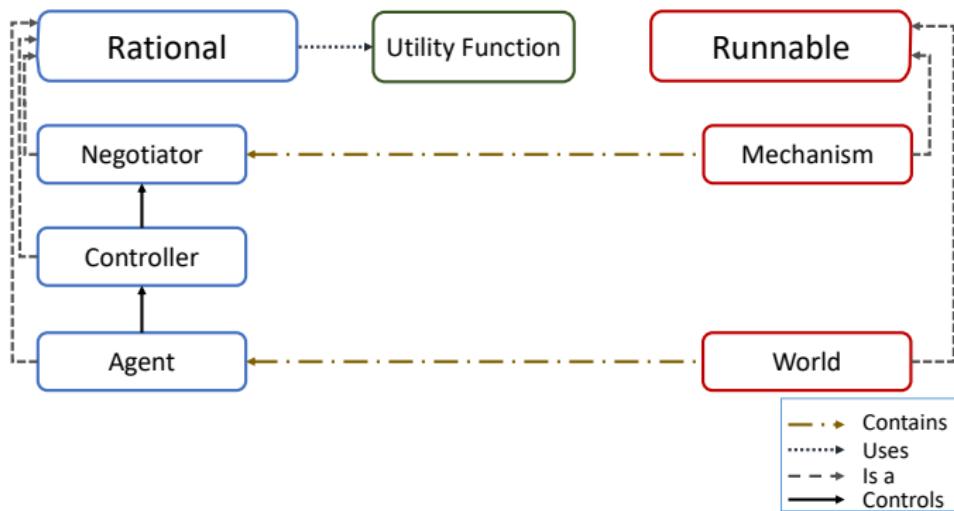

## GeniusWeb<sup>5</sup>

- An open architecture for negotiation via the internet.
- Implemented in Java with Python support for developing agents.
- Used since ANAC 2019.
- Negotiators can be distributed over multiple machines.

# Issues and Outcomes

## Cartesian Outcome Space

The Cartesian product of a set of issues:

$$\Omega = I_0 \times I_1 \times \cdots \times I_{N-1}.$$

## Issue Types

Categorical Set of values:  $\{v_i | v_i \in I\}$

Ordinal with defined order

Cardinal with defined difference

Numeric with defined numeric value  
(integer/real)

## NegMAS

```
make_os([
    make_issue(["to be", "not to be"], "the question"),
    make_issue(10),
    make_issue((0.0, 1.0)),
    make_issue([('happy', "kitten"), ("sad", "dog")])
])
```

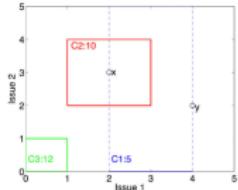

# Preferences and Utility Functions

- Partial Ordering  $\omega_i \succeq \omega_j \forall \omega_i, \omega_j \in \Omega$
- Full Ordering  $\omega_i \succ \omega_j \forall \omega_i, \omega_j \in \Omega$
- Cardinal  $\delta_{ij} = \omega_i - \omega_j \in \Re \forall \omega_i, \omega_j \in \Omega$
- Utility Function  $u(\omega) \in \Re \forall \omega \in \Omega$
- Normalized Utility Function  $u(\omega) \in [0, 1] \forall \omega \in \Omega$

- Linear UFuns  $u(\omega) = \sum_{i=0}^{|\omega|} \alpha_i \times \omega_i$
- Linear Additive UFuns  $u(\omega) = \sum_{i=0}^{|\omega|} \omega_i \times f_i(\omega_i)$
- Generalized Additive UFuns  

$$u(\omega) = \sum_{i=0}^K \omega_k \times f_k(\omega_j \forall j \in G_k)$$
- Hyper Rectangle UFuns  $u(\omega) = \sum_{k=0}^K c_k \times \delta[\omega \in C_k]$
- Genrealized Hyper Rectangle UFuns  

$$u(\omega) = \sum_{k=0}^K f_k(\omega) \times \delta[\omega \in C_k]$$

# Mediated Protocols

## Main Features

- Has A central *mediator*.
- Agents negotiate by exchanging messages with the *mediator*.
- Proposals can come from the mediator or the negotiators.

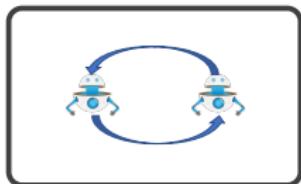

## Examples

**Single Text Protocol** The mediator proposes a single hypothetical agreements, gets feedback about it and modifies it based on this feedback.

# Unmediated Protocols

## Main Features

- No central coordinator.
- Agents negotiate by exchanging *messages*.
- All proposals come from negotiators.

## Examples

Nash Bargaining Game **Single** iteration, single issue, bilateral protocol with complete information.

Rubinstein Bargaining Protocol **Infinite** horizon, single issue, bilateral protocol with complete information<sup>a</sup>.

Alternating Offers Protocol **Finite** horizon, **multi-issue**, **multilateral** protocol with partial information<sup>b</sup>.

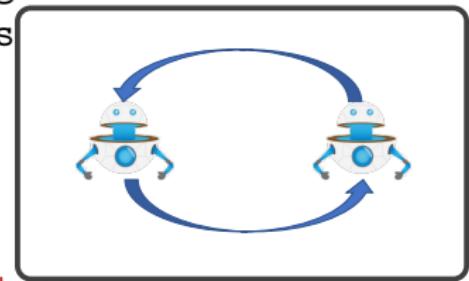

<sup>a</sup>Ariel Rubinstein, "Perfect equilibrium in a bargaining model". In: *Econometrica: Journal of the Econometric Society*

# Stacked Alternating Offers Protocol

```

n_agreed, current = 0, randint(0, n_agents)
offer = agents[current].offer()
while not timeout():
    current = (current + 1) % n_agents
    response = agents[current].res
    if response == 'accept':
        n_agreed += 1
    if n_agreed == n_agents:
        return offer
    elif response == 'end_negotiation':
        return 'failed'
    elif response == 'reject':
        offer = agents[current].offer()
return "timedout"

```

# Negotiator Components<sup>8</sup>

## BOA Architecture

**Opponent Model** Learns about the partner/opponent.

**Offer Policy** Generates new bids, Also called **Offer Policy**

**Acceptance Policy** Decides when to accept, Also called **Acceptance Policy**.

<sup>8</sup> Tim Baarslag et al. "Decoupling Negotiating Agents to Explore the Space of Negotiation Strategies". In: *Novel Insights in Agent-based Complex Automated Negotiation*. - 6 Basic Acceptance Policies
- 7 Basic Opponent Models
- 8 References

# Time-based Offer Policy

## Time-based strategies

- The negotiator's offers and decisions (acceptance, ending) depend **only** on the relative negotiation time.
- Monotonically decreasing utility (usually).
- Usually requires an inverse utility function.

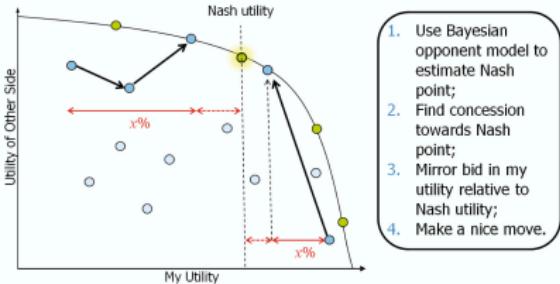

# Behavioral Offer Policies

## Behavior Based Strategies

- Responds to the opponent offers.
- Usually Tit-for-Tat.
- Usually requires an opponent model.

## (Nice) Tit-for-Tat (bilateral)<sup>9</sup>

Concede as much as the opponent toward the **estimated** nash-point and do not retaliate.

<sup>9</sup> Tim Baarslag, Koen Hindriks, and Catholijn Jonker. "A tit for tat negotiation strategy for real-time bilateral negotiations". In: *Complex Automated Negotiations: Theories, Models, and Software Competitions*. Springer, 2013, pp. 229–233.

# Outline

# Acceptance Policy

## Examples

Accept if  $\alpha u(\omega) + \beta$  is greater than:

**Threshold** a utility threshold ( $\tau$ ).

**Constant** May be a fraction of maximum utility ( $AC_{const}(\gamma)$ ).

**Time-based** Monotonically non-increasing with time ( $AC_{monotonic}(t)$ ).

**Last** my last offer ( $AC_{last}$ ).

**Next** what I am about to offer ( $AC_{next}$ ).

**Best** the best offer I received in a given window ( $AC_{best}(K)$ ).

**Average** the average utility I received in a given window ( $AC_{avg}(K)$ ).

**Time** the reserved value and  $T \in [0, 1]$  fraction of the negotiation have passed ( $AC_{time}(T)$ )

**Expected** the best offer I expect to receive (e.g. Gaussian Processes,

# Combining Acceptance Policies

## Combined Acceptance Strategy<sup>10</sup>

- Combines multiple simple acceptance policies.
- $AC_{combi}(\tau, \gamma) = AC_{next} \vee (AC_{time}(\tau) \wedge AC_{const}(\gamma))$
- $AC_{combi}^{best}(\tau, W) = AC_{next} \vee (AC_{time}(\tau) \wedge AC_{best}(W))$
- $AC_{combi}^{avg}(\tau, W) = AC_{next} \vee (AC_{time}(\tau) \wedge AC_{avg}(W))$
- $AC_{combi}^{best}(\tau) = AC_{next} \vee (AC_{time}(\tau) \wedge AC_{best}(T))$

## NegMAS

```

ACCombi = ACNext() or (ACtauime(tau) and ACCConst(gamma))
ACBest = ACNext() or (ACtauime(tau) and ACLastKReceived(K))
ACAvg = ACNext() or (ACtauime(tau) and ACLastKReceived(K, op=)
ACBestAll = ACNext() or (ACtauime(tau) and ACLastKReceived())

```

# RLBOA: Learning Offering Strategy<sup>2</sup>

## Main Points

- Extends the BOA architecture.
- Learns only a bidding strategy:
  - The agent learns how to move *in its own utility axis*.

<sup>2</sup>Jasper Bakker et al. "RLBOA: A modular reinforcement learning framework for autonomous negotiating agents". In: *Proceedings of the 18th international conference on autonomous agents and multiagent systems*. 2019, pp. 260–268.

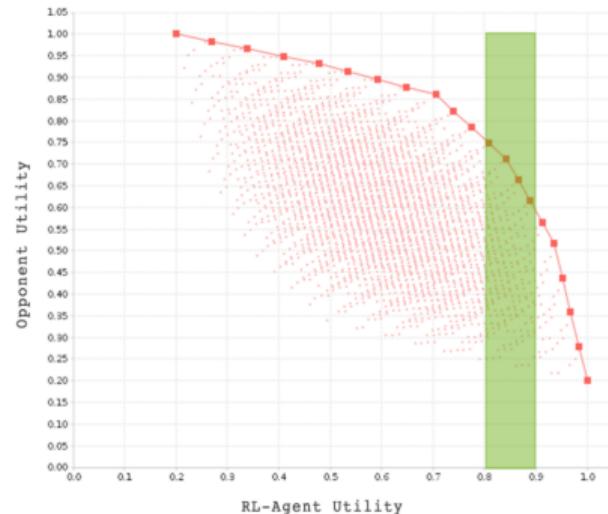

# RLBOA: The details

- **State Space:**  $\{\hat{u}(\omega_t^s), \hat{u}(\omega_{t-1}^s), \hat{u}(\omega_t^p), \hat{u}(\omega_{t-1}^p), t\}$ .
- $\hat{u}(\omega) = [N \times u(\omega)]^3$
- **Action Space:**  $\leftarrow, -, \rightarrow$ .
- First step  $\rightarrow i \in [0, N - 1]$
- Out-of-boundary correction:  $-$ .
- **Training Method:** Q-learning
- **Acceptance Strategy [Recommended]:**  
 $AC_{next}(\alpha = 1, \beta = 0)$ <sup>4</sup>

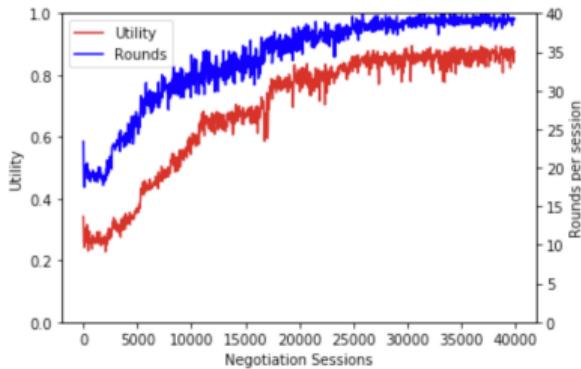

$$a(\omega) = \begin{cases} \text{Accept}, & \text{if } \alpha u(\omega) + \beta \geq u(o(s)) \\ \text{Reject}, & \text{otherwise} \end{cases}$$

<sup>4</sup>Just ignore the special case at  $u == 1$ .

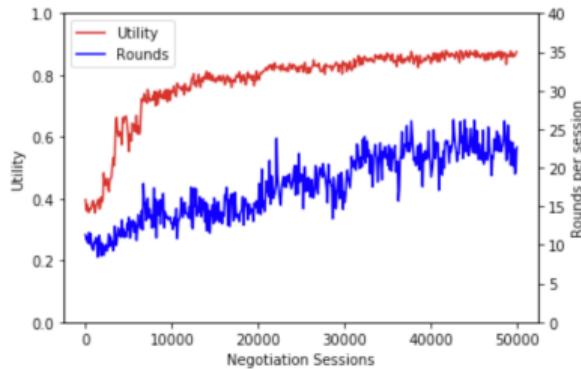

<sup>4</sup>Default acceptance strategy in NegMAS

# RLBOA: Evaluation and Results

(a) Scenario generality experiment against the Boulware agent.

(b) Opponent generality experiment in the medium sized domain with low opposition.

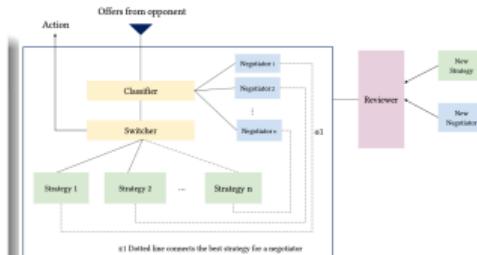

- Partners: TFT, Boulware TB
- Projection into one's utility space is surprisingly effective.
- Faster and better agreements!

Domain	Outcome space	Low opp.	High opp.
Small	256	0.2615	0.5178
Medium	3.125	0.3111	0.5444
Large	46.656	0.2595	0.5250

# A Framework for Learning Offer Strategies

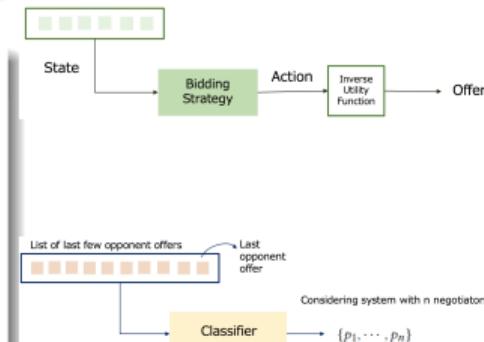

## Main Idea<sup>5</sup>

- Uses RL for learning **approximate best responses** to some agents.
- Uses Supervised Learning to learn a **realtime switching strategy** between learned best responses.
- Uses a form of Unsupervised Learning for **adapting the system to new partner types**.

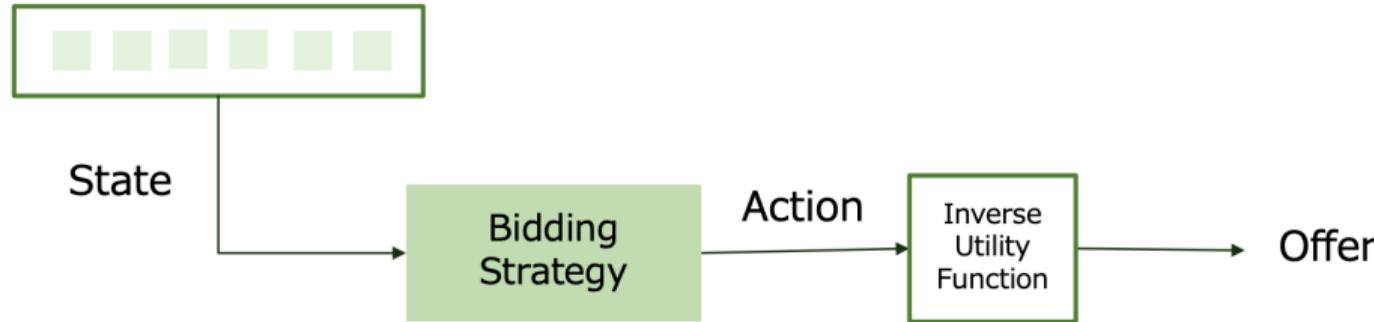

## Phases

- **Before Negotiation** Learn approximate best responses to **a few agents**.
- **During Negotiation** Switch to the most appropriate **learned app. best response**
- **After Negotiation** Decide whether to add a new **best response**.

<sup>5</sup>Ayan Sengupta, Yasser Mohammad, and Shinji Nakada. "An Autonomous Negotiating Agent Framework with Reinforcement Learning Based Strategies and Adaptive Strategy Switching".

# Before: Learning Approximate Best Response

State

Bidding  
Strategy

Action

Inverse  
Utility  
Function

Offer

## The RL Component

**State** Self utility of last N offers plus relative time.

**Action** Utility of next offer  $\in [0, 1]$ .

**Reward** Agreement/disagreement utility.

**Trainer** Soft Actor Critic (SAC)

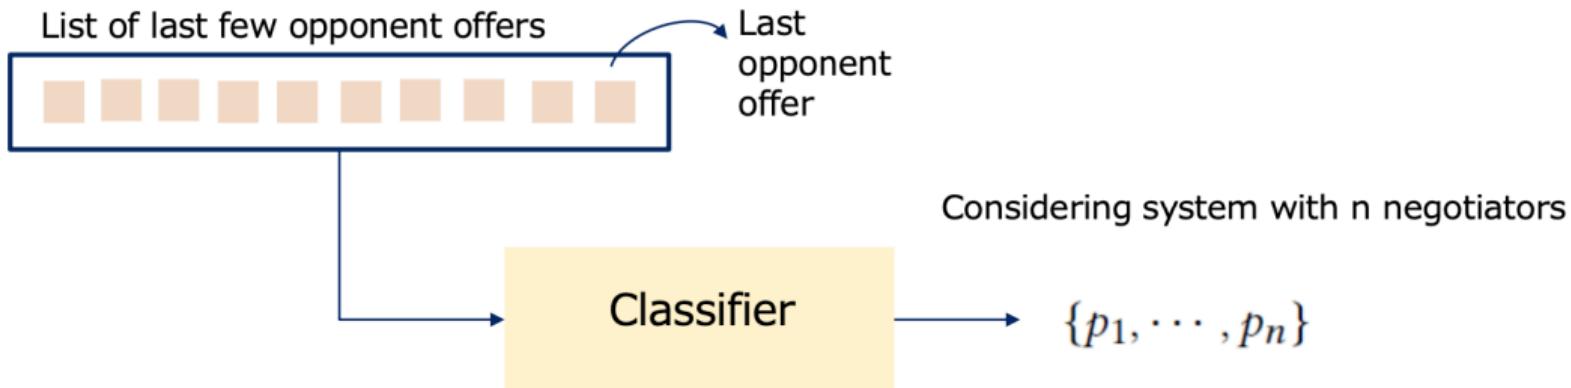

$$s_t = \{t_r, U_s(\omega_s^{t-2}), U_s(\omega_o^{t-2}), U_s(\omega_s^{t-1}), \\ U_s(\omega_o^{t-1}), U_s(\omega_s^t), U_s(\omega_o^t)\}$$

$$a_t = u_s^{t+1} \text{ such that } u_r < u_s \leq 1$$

$$U_s^{-1}(u_s) = \underset{\omega}{\operatorname{argmin}} f(\omega), \text{ where}$$

$$f(\omega) = (U_s(\omega) - u_s)^2 \quad \forall \omega \in \Omega.$$

# During: Learning realtime Partner Classification

## The SL Components

**Features** Opponent last  $K$  offers.

**Target** Opponent Type (discrete set)

# After: Reviewing New Pairs

## New Partner Type ( $N_{new}$ ) Encountered

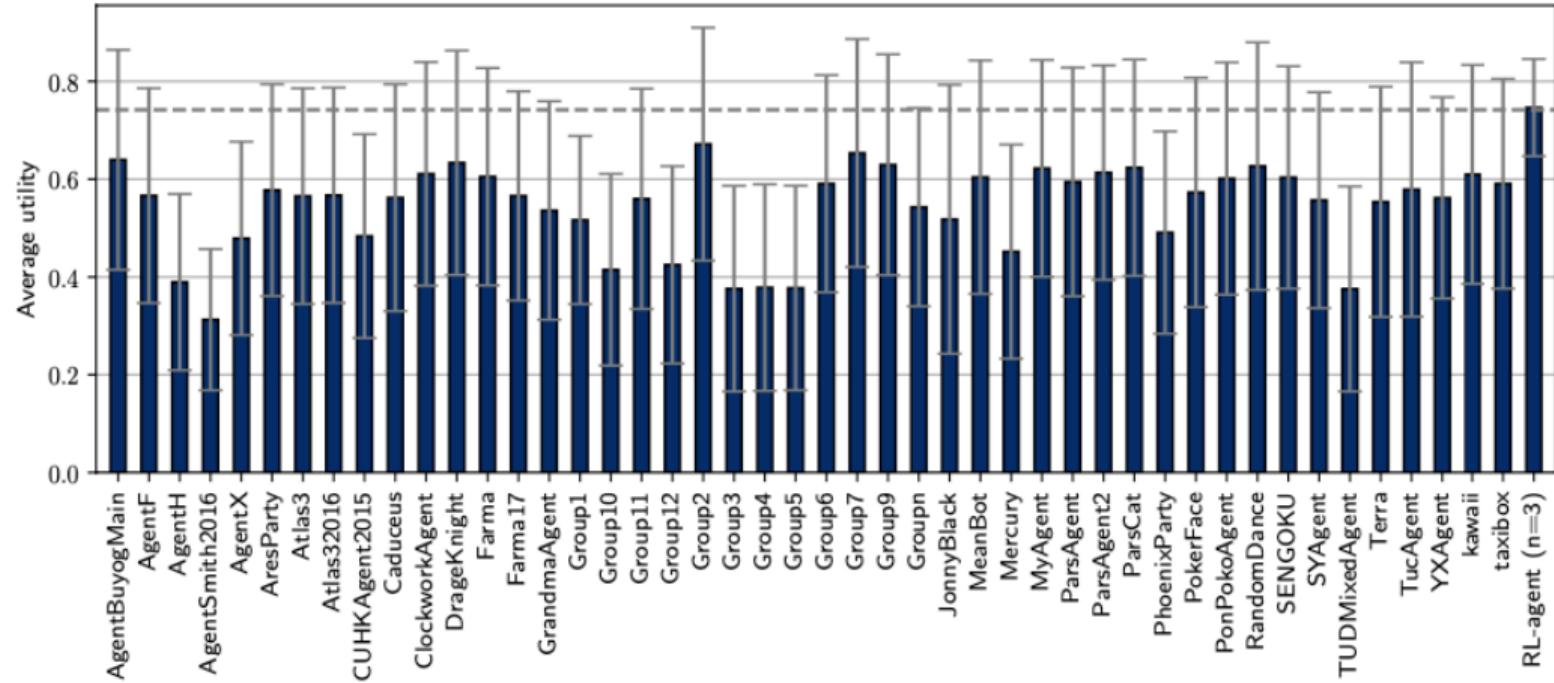

- Train a best response (using SAC)  $\rightarrow S_{new}$ .
- Evaluate  $S_{new}$  against  $N_{new} \rightarrow U(S_{new})$
- Evaluate *Current* against  $N_{new} \rightarrow U(Current)$
- Add  $(S_{new}, N_{new})$  iff  $\beta U(Current) < U(S_{new})$
- Update best responses ↓.

## Update Best Responses

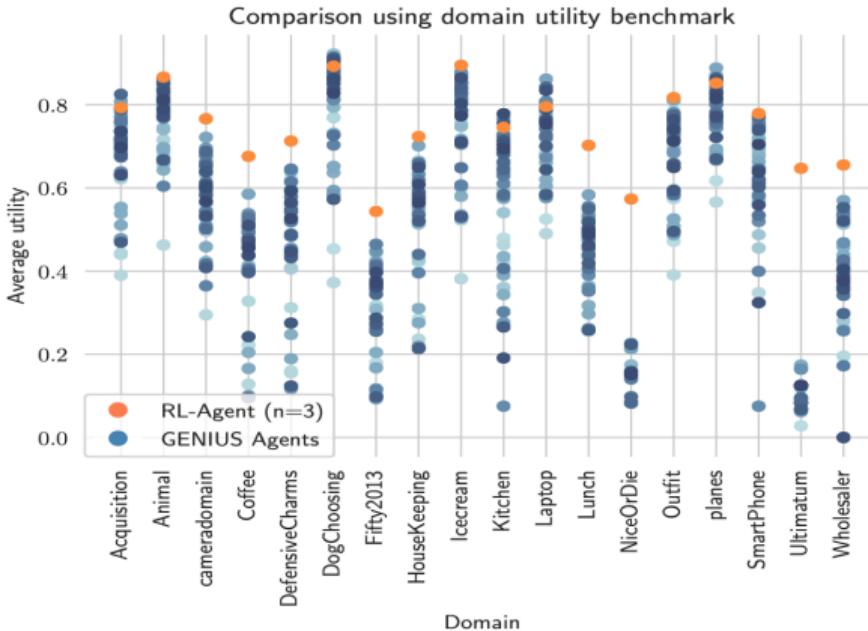

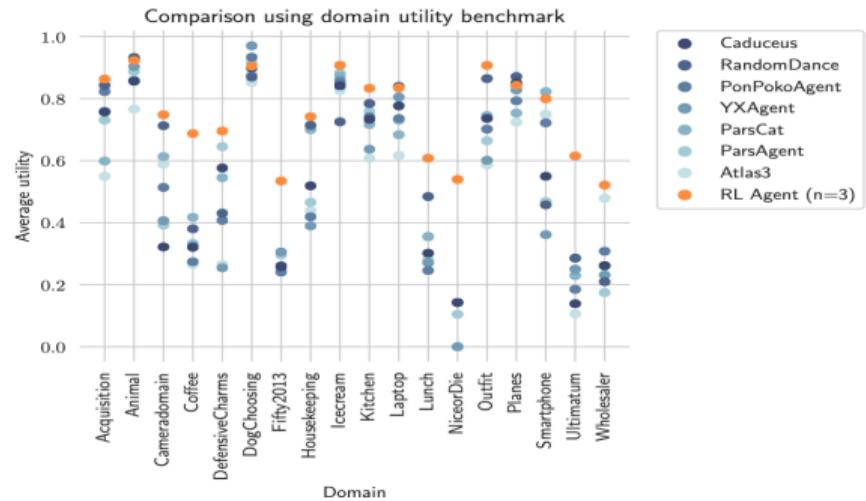

- For every learned ABR, negotiator pair  $(S, N)$ :
  - Evaluate  $S_{new}$  against  $N \rightarrow U(S_{new})$
  - Evaluate  $S$  against  $N \rightarrow U(S)$
  - Replace  $S$  with  $S_{new}$  iff  $\alpha U(S) < U(S_{new})$

# Results: Against Different Opponents

Comparison using self utility benchmark

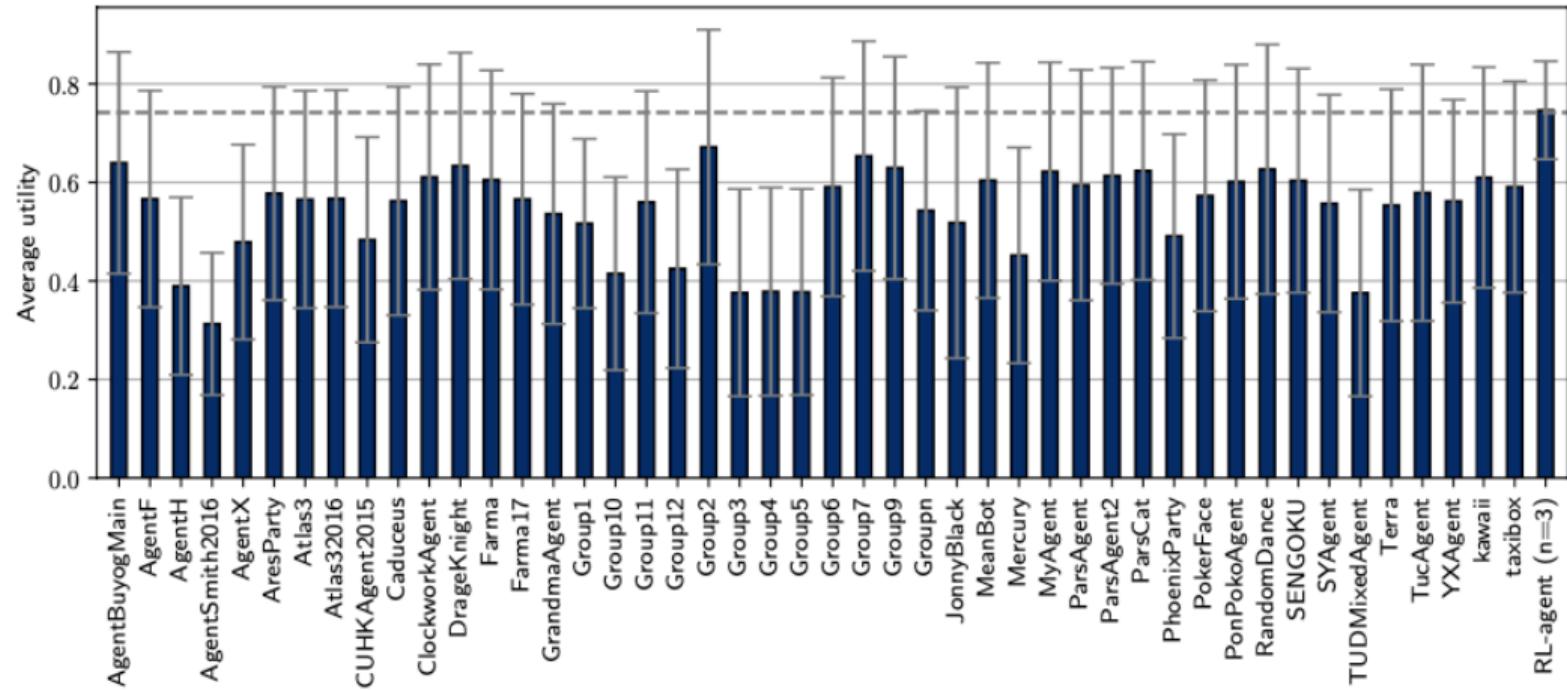

# Results: In Different Domains

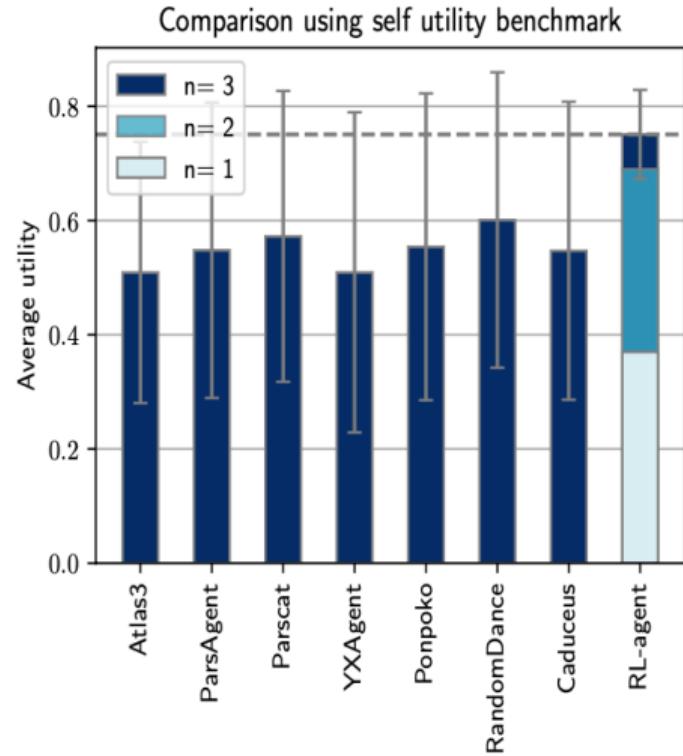

# Results: Compared with SOTA Agents

Comparison using self utility benchmark

# Results: Improvement with new best responses

# DQN for learning Acceptance Strategy<sup>6</sup>

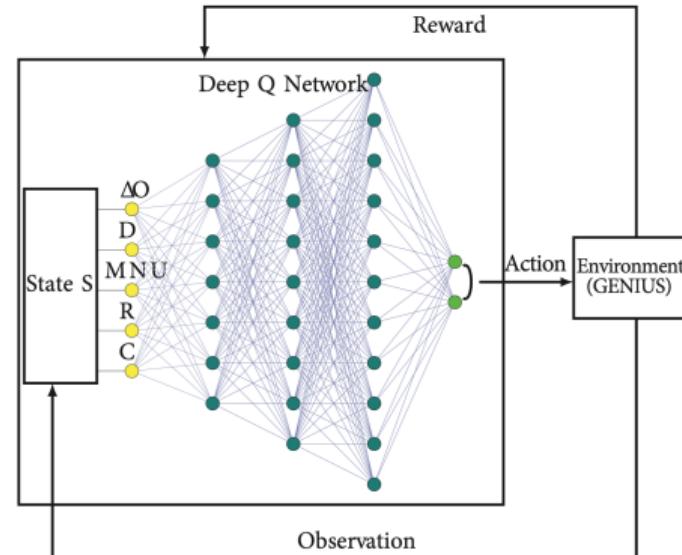

## Main Idea

- Learning the acceptance strategy for a fixed offering strategy.

## Settings

- State Space**  $u(\omega) - u(\phi), 1 - t, u(o(s)), u_t, u(\omega)$ 
  - $u_t$  is a relatively large target utility (e.g. 0.8).
- Action Space** Accept/Reject
- Reward**

$$r = \begin{cases} -2|u_t - u_f|, & \text{if } u_t > u(\omega_a) \\ +2|u_t - u_f|, & \text{if } u_t < u(\omega_a) \\ 0 & \text{if non-terminal} \end{cases}$$

# HardHeaded Opponent Modeling Strategy<sup>8</sup>

## Context

- Winner of the ANAC 2011 competition.

$$u(\omega) = \sum_{i=1}^n \alpha_i F[i, \omega_i]$$

- Assumes a Discrete Outcome Space, Linear Additive Utility Function and a bilateral negotiation.
- Learns while negotiating.

## Main Idea

- The opponent is likely to change values for issues that are less important.

<sup>8</sup>Thijs van Krimpen, Daphne Looije, and Siamak Hajizadeh. "HardHeaded". In: *Complex Automated Negotiations: Theories, Models and Software Competitions*. Ed. by Ito Takayuki et al. Springer, 2013, pp. 223–227.

# HardHeaded Opponent Model: Pseudo-code

```
# M issues and N values per issue
F, alpha = np.zeros((M, N)), np.zeros(M)
epsilon, last_offer = 0.02, None
def after_receiving(self, state, offer): # update model
    if not self.last_offer:
        self.last_offer = offer
        return
    for i in range(M):
        if offer[i] != self.last_offer[i]:
            continue
        self.F[i, offer[i]] += 1
        self.alpha[i] += self.epsilon
    self.alpha /= self.alpha.sum()

def eval(self, offer): # estimate partner's utility value
    return self.alpha * self.F[:, offer]
```

# Opponent Model: Bayesian

## Bayesian Learning

**Hypothesis** A hypothesis about the opponent's behavior.

# Opponent Model: Bayesian

## Bayesian Learning

**Hypothesis** A hypothesis about the opponent's behavior.

**Evidence** Behavior of the agent (e.g. its counteroffers/rejections).

# Opponent Model: Bayesian

## Bayesian Learning

**Hypothesis** A hypothesis about the opponent's behavior.

**Evidence** Behavior of the agent (e.g. its counteroffers/rejections).

$$P(H|E) = \frac{P(E|H)P(H)}{P(E)}$$

# Opponent Model: Bayesian

## Bayesian Learning

**Hypothesis** A hypothesis about the opponent's behavior.

**Evidence** Behavior of the agent (e.g. its counteroffers/rejections).

$$P(H|E) = \frac{P(E|H)P(H)}{P(E)}$$

## Example

**Hypothesis space:** Utility function as a weighted sum of basis functions

$$u(\omega) = \sum_{i=1}^n \alpha_i f_i(\omega_i; \sigma_i)$$

# Opponent Model: Bayesian

## Bayesian Learning

**Hypothesis** A hypothesis about the opponent's behavior.

**Evidence** Behavior of the agent (e.g. its counteroffers/rejections).

$$P(H|E) = \frac{P(E|H)P(H)}{P(E)}$$

## Example

**Hypothesis space:** Utility function as a weighted sum of basis functions

$$u(\omega) = \sum_{i=1}^n \alpha_i f_i(\omega_i; \sigma_i)$$

**Evidence:** Rejection and offers (assuming a strategy).

# Bayesian Opponent Model Learner<sup>9</sup>

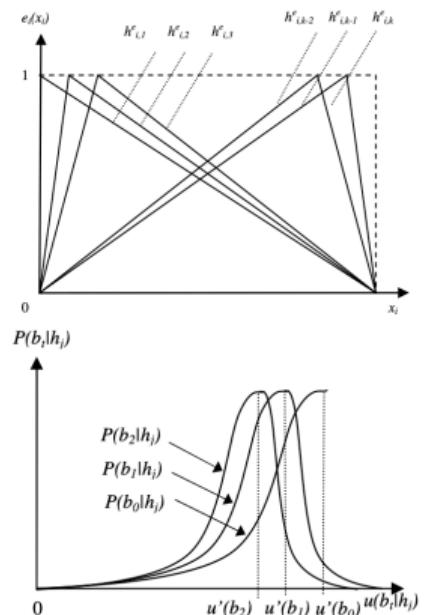

## Assumptions

- Opponent has a Linear Additive UFun ( $u(\omega) = \sum_{i=1}^{|\omega|} \alpha_i f_i(\omega_i, \sigma_i)$ )
- Value functions ( $f_i$ ) are triangle like (or linear).

## Settings

- Hypothesis Space: values of  $\alpha_i$  and  $\sigma_i$
- Evidence:  $P(\omega|\alpha_i, \sigma_i) = \frac{1}{\sqrt{2\pi}\sigma} \exp \frac{(u(\omega|\alpha_i, \sigma_i) - \hat{u}(\omega))^2}{\sigma^2}$  with  $\hat{u}(\omega) = 1 - \frac{t}{20}$ .
- Estimated opponent utility value:  

$$u^o(\omega) = \sum_{j=1}^{|H|} P(\alpha_j, \sigma_j | \Omega^o) u(\omega | \alpha_j, \sigma_j)$$

# Preference Elicitation

## The challenge

How to reduce Uncertainty in user preferences:

- before negotiation (offline preference elicitation).
- while negotiating (online preference elicitation).

# Preference Elicitation

## The challenge

How to reduce Uncertainty in user preferences:

- before negotiation (offline preference elicitation).
- while negotiating (online preference elicitation).

## Types of questions

Utility Value what is  $\tilde{u}(\omega)$ ?

Utility Constraint Is  $\tilde{u}(\omega) \geq x$ ? Usually implemented as a standard gamble.

Utility Comparison Is  $\omega_1 \succ \omega_2$ ?

# Elicitation Procedures

- ① Long history in the decision support and economics research community.
- ② Take away message: .

# Elicitation Procedures

- ① Long history in the decision support and economics research community.
- ② Take away message: **Do not ask about the utility directly..**

# Elicitation Procedures

- ① Long history in the decision support and economics research community.
- ② Take away message: **Do not ask about the utility directly..**
- ③ Practical elicitation uses a **series** of comparisons between outcomes to assess utilities.

# Elicitation Procedures

- ① Long history in the decision support and economics research community.
- ② Take away message: **Do not ask about the utility directly..**
- ③ Practical elicitation uses a **series** of comparisons between outcomes to assess utilities.

## A Gamble

$(\omega^*, \omega_*, p)$  : Getting  $\omega^*$  with probability  $p$  otherwise  $\omega_*$

# Elicitation Procedures

- ① Long history in the decision support and economics research community.
- ② Take away message: **Do not ask about the utility directly..**
- ③ Practical elicitation uses a **series** of comparisons between outcomes to assess utilities.

## A Gamble

$(\omega^*, \omega_*, p)$  : Getting  $\omega^*$  with probability  $p$  otherwise  $\omega_*$

## Example query

Do you prefer to get  $\omega$  for certain over  $(\omega^*, \omega_*, p)$ ?

# Elicitation Procedures/Strategies

## Probability Equivalence

find  $p$  so that  $\omega = (\omega^*, \omega_*, p)$

## Certainty Equivalence

find  $\omega$  so that  $\omega = (\omega^*, \omega_*, p)$

- Both require *normalized* utilities.
- Both require knowledge of  $\omega^* \succ \omega \succ \omega_*$ .
- Lead to different biases.

## Comparison-only Procedures

① Titration-down:  $p_k = 1 - s \times k$

② Titration-up:  $p_k = s \times k$

③ Ping-pong:  $p_k = \begin{cases} s \times \lfloor k/2 \rfloor & k \text{ is odd} \\ 1 - s \times k/2 & k \text{ is even} \end{cases}$

# Importance of Elicitation

## Negotiation with Elicitation

$$m, \Omega, R, \tilde{U}_i \forall 1 \leq i \leq m, \hat{U}_i^0 \forall 1 \leq i \leq m$$

*m* Number of agents/actors

$\Omega = \{\omega_j\}$  Possible outcomes (assumed countable)

*n* Number of outcomes  $|\Omega|$

$R(i) \equiv r_i$  Reserved value for agent *i*

$\tilde{U}_i : \Omega \rightarrow [0, 1]$  Utility of outcomes to **actor** *i*

$\hat{U}_i^0 : \Omega \rightarrow P$  Probability distribution of utility values for **agent** *i*

$$\hat{U}_{ij}^0 \equiv \hat{U}_i^0(\omega_j)$$

$P : \{[0, 1] \rightarrow [0, 1]\}$  A probability distribution on the closed interval  $[0, 1]$

## What is Elicitation Doing?

Reduces uncertainty in  $\hat{U}$

# State of the Art

- Lots of work on preferences/utility elicitation in decision making domain.
- Some work on incremental utility elicitation.
- Few works on incremental utility elicitation during negotiations

# State of the Art

- Lots of work on preferences/utility elicitation in decision making domain.
- Some work on incremental utility elicitation.
- Few works on incremental utility elicitation during negotiations

## Why Is Negotiation Different

- ① The acceptance model changes over time → environment dynamics are not static.
- ② Exploration is extremely costly.
- ③ Usually negotiations are not repeated much.
- ④ Cannot train on a simulator (in most cases).

# Value of Information Algorithm

- Based on<sup>10</sup> in decision-support context.
- Adapted to the negotiation context.

## Main Idea

- Assume an accurate opponent model (acceptance probability)
- Given a set of queries  $Q \rightarrow$  find the one with the maximum difference between the expected expected utility before and after asking it<sup>1112</sup>.

# VOI Based Elicitation

## Policy

$\pi^t = (\omega^t, \omega^{t+1}, \dots, \omega^N)$  where  $\omega^x \in \Omega$   $K(\omega|\pi) \equiv$  index of  $\omega$  in  $\pi$ ,  $\pi(k) = \omega$  where  $K(\omega|\pi) = k$

## Optimal Policy

$$\pi^{t*} = \arg \max_{\pi} EEU^t \left( \pi, \left\{ \hat{U}_{\omega}^t \right\} \right)$$

# VOI Based Elicitation

## Policy

$\pi^t = (\omega^t, \omega^{t+1}, \dots, \omega^N)$  where  $\omega^x \in \Omega$   $K(\omega|\pi) \equiv$  index of  $\omega$  in  $\pi$ ,  $\pi(k) = \omega$  where  $K(\omega|\pi) = k$

## Probability of Agreement

$$Pa^t(\omega|\pi) = \begin{cases} \Lambda^t(\omega) \prod_{k=1}^{K_\pi(\omega)-1} (1 - \Lambda^t(\pi(k))) & \omega \in \pi \\ 0 & \text{otherwise} \end{cases}$$

## Optimal Policy

$$\pi^{t*} = \arg \max_{\pi} EEU^t \left( \pi, \left\{ \hat{U}_{\omega}^t \right\} \right)$$

# VOI Based Elicitation

## Policy

$\pi^t = (\omega^t, \omega^{t+1}, \dots, \omega^N)$  where  $\omega^x \in \Omega$   $K(\omega|\pi) \equiv$  index of  $\omega$  in  $\pi$ ,  $\pi(k) = \omega$  where  $K(\omega|\pi) = k$

## Probability of Agreement

$$Pa^t(\omega|\pi) = \begin{cases} \Lambda^t(\omega) \prod_{k=1}^{K_\pi(\omega)-1} (1 - \Lambda^t(\pi(k))) & \omega \in \pi \\ 0 & \text{otherwise} \end{cases}$$

## Expected Expected Utility<sup>13</sup>

$$EEU^t\left(\pi, \left\{ \hat{U}_\omega^t \right\}\right) = \sum_{\omega \in \Omega} Pa(\omega|\pi) \mathbb{E}\left(\hat{U}_\omega^t\right)$$

## Optimal Policy

$$\pi^{t*} = \arg \max_{\pi} EEU^t\left(\pi, \left\{ \hat{U}_\omega^t \right\}\right)$$

# VOI Based Elicitation II

## Questions

$$Q \equiv \{q_I\}$$
$$q_I \equiv \{(Ans_s^I, p_s)\}$$

## Answers

$$Ans_s^I \equiv \{\hat{U}_\omega^{t+1}\}$$
$$\sum_s p_s = 1$$

# VOI Based Elicitation II

## Questions

$$Q \equiv \{q_I\}$$

$$q_I \equiv \{(Ans_s^I, p_s)\}$$

## Answers

$$Ans_s^I \equiv \{\hat{U}_\omega^{t+1}\}$$

$$\sum_s p_s = 1$$

## Expected value of information

$$EVOI(q', \{\hat{U}_\omega^t\}) = \mathbb{E}_s (\max_{\pi} EEU(\pi, Ans_s')) - \max_{\pi} EEU(\pi, \{\hat{U}_\omega^t\})$$

# VOI Based Elicitation II

## Questions

$$\begin{aligned} Q &\equiv \{q_I\} \\ q_I &\equiv \{(Ans_s^I, p_s)\} \end{aligned}$$

## Answers

$$\begin{aligned} Ans_s^I &\equiv \{\hat{U}_\omega^{t+1}\} \\ \sum_s p_s &= 1 \end{aligned}$$

## Expected value of information

$$EVOI(q', \{\hat{U}_\omega^t\}) = \mathbb{E}_s (\max_{\pi} EEU(\pi, Ans_s')) - \max_{\pi} EEU(\pi, \{\hat{U}_\omega^t\})$$

## Elicitation

Ask  $q^*$  where

$$q^* = \arg \max_q (EVOI(q', \{\hat{U}_\omega^t\}) - c_q)$$

$c_q$  Cost of asking question  $q$

# VOI main Issues

## Accurate Agreement Model Assumption

- Everything depends on the probability of agreement ( $Pa$ )
- $Pa$  depends on the **product** of probabilities in the acceptance model ( $\Lambda^t$ )

$$Pa^t(\omega|\pi) = \begin{cases} \Lambda^t(\omega) \prod_{k=1}^{K_\pi(\omega)-1} (1 - \Lambda^t(\pi(k))) & \omega \in \pi \\ 0 & \text{otherwise} \end{cases}$$

# VOI main Issues

## Accurate Agreement Model Assumption

- Everything depends on the probability of agreement ( $Pa$ )
- $Pa$  depends on the **product** of probabilities in the acceptance model ( $\Lambda^t$ )

$$Pa^t(\omega|\pi) = \begin{cases} \Lambda^t(\omega) \prod_{k=1}^{K_\pi(\omega)-1} (1 - \Lambda^t(\pi(k))) & \omega \in \pi \\ 0 & \text{otherwise} \end{cases}$$

Speed: Complexity =  $O(nN|Q||Ans|)$

- Too many *argmax* and  $\mathbb{E}$  operations.
- Every policy extends to the end of the negotiation.

$$q^* = \arg \max_q \left( EVOI \left( q', \left\{ \hat{U}_\omega^t \right\} \right) - c_q \right)$$

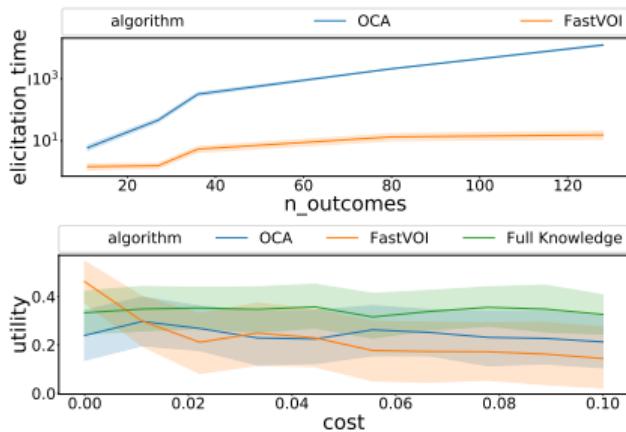

$$EVOI \left( q', \left\{ \hat{U}_\omega^t \right\} \right) = \mathbb{E}_s \left( \max_\pi EEU \left( \pi, Ans_s' \right) \right) - \max_\pi EEU \left( \pi, \left\{ \hat{U}_\omega^t \right\} \right)$$

$$\pi^{t*} = \arg \max_\pi EEU^t \left( \pi, \left\{ \hat{U}_\omega^t \right\} \right)$$

- $L_1$  factories/agents receive exogenous sales of **final product**.

# Overview

- A **production-graph** defines what can be produced and how.
- We have 3 products, 2 processes.
- Factories can run **manufacturing processes** converting input products into output products on their **production lines**.
- We have two layers of factories/agents.
- $L_0$  factories/agents receive exogenous supplies of **raw material**.
- $L_1$  factories/agents receive exogenous sales of **final product**.
- $L_0$  negotiate with  $L_1$  agents to exchange **intermediate product**

# SCML-OneShot Track

## Main Idea

- Agents arranged in two production levels (3 products, 2 processes)
- Every day you get a **fresh set** of exogenous contracts.
- All products perish in one day (no inventory accumulation).

# Utility Function

## General Form

Utility = Profit = Sales - Supply cost - Production cost - Disposal cost - Delivery Penalty

Sales unit price  $\times$  quantity  $\forall$  feasible sales.

Supply cost unit price  $\times$  quantity  $\forall$  supplies.

Production cost unit production cost  $\times$  quantity produced.

Disposal cost unit disposal cost  $\times$  quantity bought but not produced.

Shortfall penalty unit shortfall penalty  $\times$  infeasible sales.

# Information about self

## Static Information

- Number of production lines.
- Production cost.
- Mean and variance of disposal cost and shortfall penalty.
- Input/output product, consumers/suppliers, n. input/output negotiations.

## Dynamic Information

- current input/output negotiation issues.
- current input/output exogenous contracts (quantity, unit price).
- current disposal cost and shortfall penalty.
- Current balance (money in wallet).

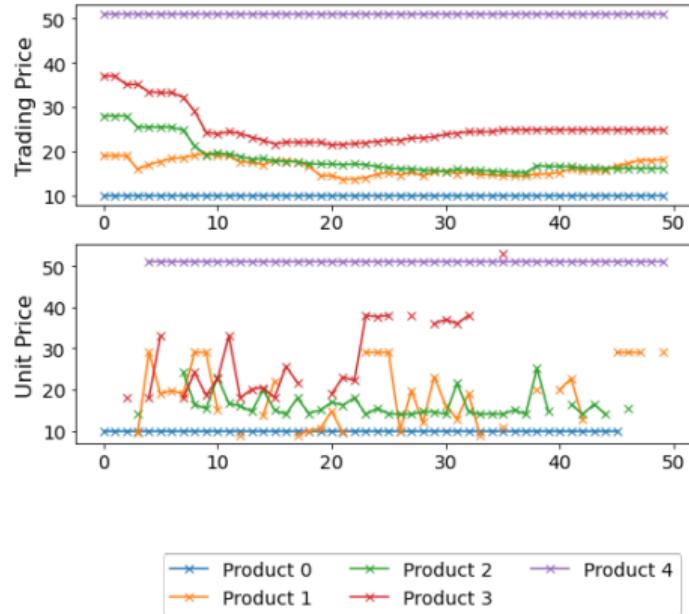

# Market Information

## Trading prices

- Trading prices represent a weighted running average of different product prices.
- Available to the agent through the AWI in all tracks.

## Exogenous Contract Summary

- The total quantity and average prices of all exogenous contracts are now available through the AWI.
  - Exogenous contracts for individual agents are private information.

# Other Agents' Information

## Financial Reports

For each agent, a financial report is published every  $m$  days (e.g. 5) with the following information:

- Current balance (money in wallet).
- breach probability (fraction of sale contracts not satisfied).
- breach level (average fraction of sales not satisfied).

# Double Oracle Algorithm<sup>3</sup>(PSRO<sup>4</sup>)

**Theorem** The double oracle algorithm converges to a Nash equilibrium in zero-sum games.

## Algorithm 1 Double Oracle Algorithm

**Input:** A game with strategy sets  $\Pi_i$ , for  $i \in \{1, 2\}$

**Input:** An initial strategy set  $\Pi_i^0 \in \Pi_i$ , for  $i \in \{1, 2\}$

**Output:** Nash equilibrium

- 1: **repeat**  $t \in \{0, 1, 2, \dots\}$
- 2:     Find  $\pi^*$ , a Nash equilibrium in the game  $\Pi_i^t$ , for  $i \in \{1, 2\}$
- 3:     **for**  $i \in \{1, 2\}$  **do**
- 4:         Find a best response  $\beta_i \in \Pi_i$  to  $\pi_{-i}^*$
- 5:         Expand strategy set:  $\Pi_i^{t+1} \leftarrow \Pi_i^t \cup \beta_i$
- 6: **until**  $\Pi_i^{t+1} = \Pi_i^t$ , for  $i \in \{1, 2\}$
- 7: **Return:**  $\pi^*$

# Finding a Best Response to a Fixed Opponent

## Learning a best-response policy, offline

- Fixed acceptance policy: use RL to learn an offer policy
- Fixed offer policy: use deep learning to learn an acceptance policy

# Finding a Best Response to a Fixed Opponent

## Learning a best-response policy, offline

- Fixed acceptance policy: use RL to learn an offer policy
- Fixed offer policy: use deep learning to learn an acceptance policy

## Some issues with this approach

- Why decouple these decisions? Doing so is unlikely to be optimal. Perhaps for tractability?
- Possible way out: Formulate as an MDP and solve
- An even bigger problem: when is a negotiating partner so benevolent that they give you access to a simulator of their strategy that you can run for thousands of iterations to learn a best response?
- Possible way out: EGTA

# Negotiation as an MDP

Assume a **fixed** opponent: one's whose strategy does depend *not* on our actions.  
E.g., an **aspiration** agent.

When the opponent is known, our agent's decision making problem is an **MDP**.

- States: negotiation round plus two designated states, agreement and disagreement
- Actions: offers and accept/reject
- Transitions: capture opponent's behavior (e.g., if they accept, transition to the agreement state)
- Rewards: zero everywhere except at agreement, where they are given by the agent's utility function

Solving MDPs:

- Planning (e.g., VI), if the opponent model is in closed form
- RL, if we have only a generative model of the opponent model

# Opponent Model

An opponent model comprises **an acceptance model** and **an offer policy**.

(Opponent ufuns are not modelled, because our decisions are conditionally independent of them, given an acceptance model and an offer policy.)

**TDAM:** time-dependent acceptance model

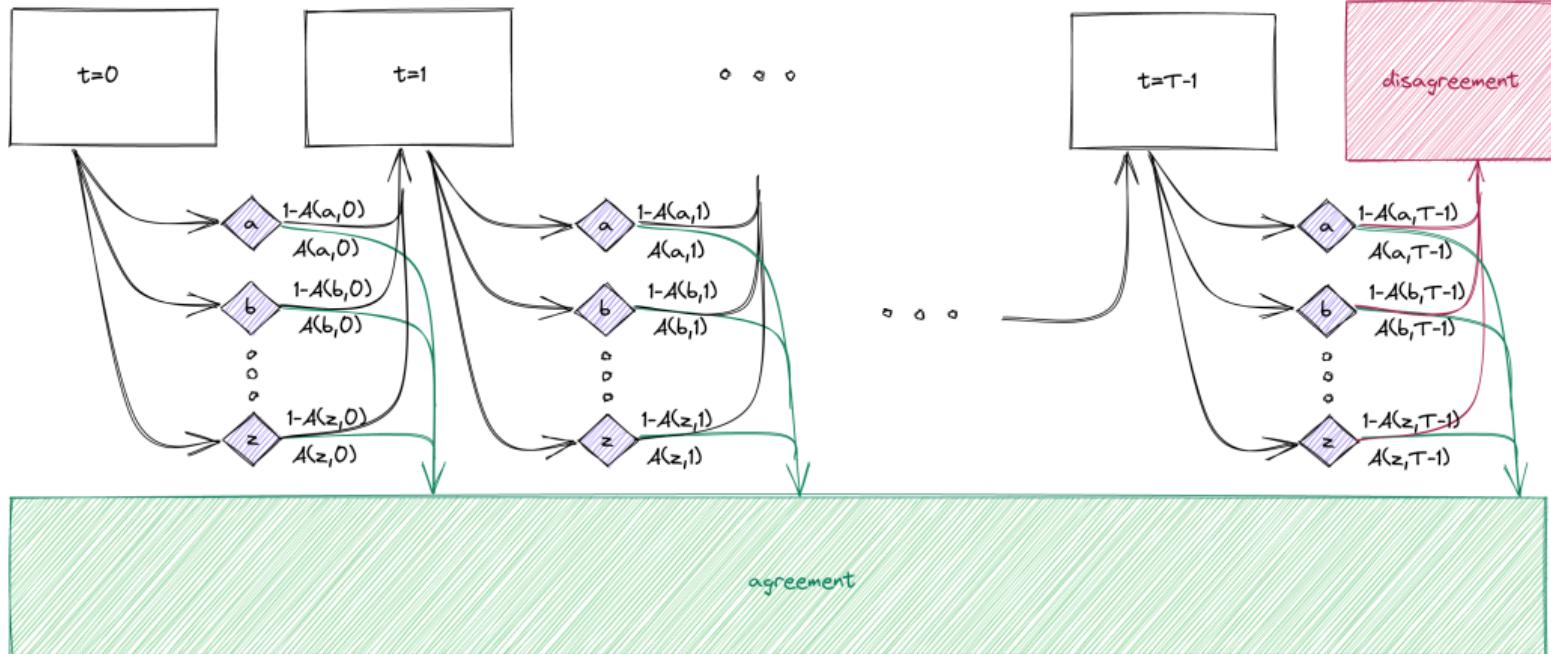

A map from a time to an acceptance probability distribution

**TDOP:** time-dependent offer policy

A map from a time to opponent offers (or probabilities over offers)

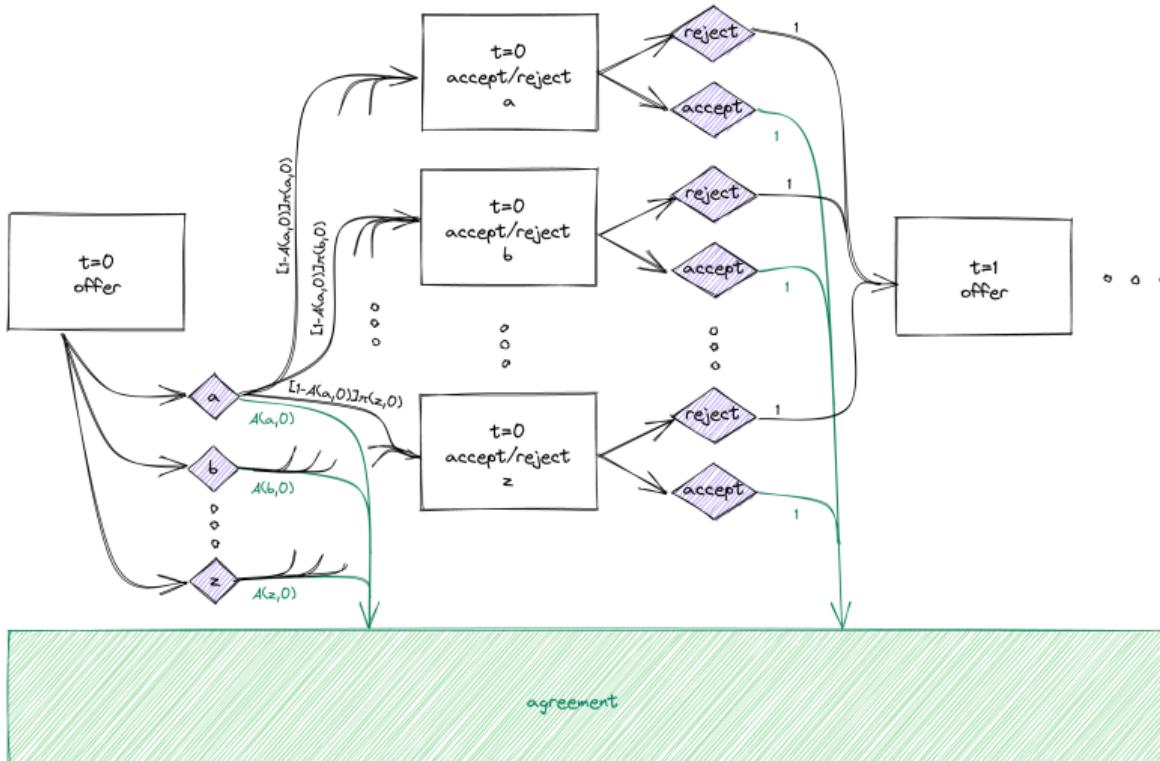

Time = negotiation round.

## TDAM MDP

## TDAM + TDOP MDP

Drawing by Jackson de Campos

Y. Mohammad and A. Greenwald (NEC and Brown)

Automated Negotiation: Challenges and Tools

# EGTA, Revisited

- Goal of EGTA: build agents that are robust, against a population of opponents.
- Each TDAM + TDOP MDP corresponds to an opponent.  
A solution to each MDP is an optimal negotiation strategy for playing against that opponent.
- Start from an initial population of opponents (i.e., MDPs)  $\Rightarrow$  negotiation strategies.
- Use EGTA to grow the population of negotiation strategies  $\Rightarrow$  opponents (i.e., MDP).
- End result should be a robust agent!

# Concurrent Negotiations

These negotiations are dependent, as evidenced by the global ufun  $u$ , which depends on a global outcome: i.e., the outcomes of all negotiations.

The problem of how to negotiate in this setting is reminiscent of how to bid in simultaneous auctions, when bidders' utilities are combinatorial.<sup>5</sup>

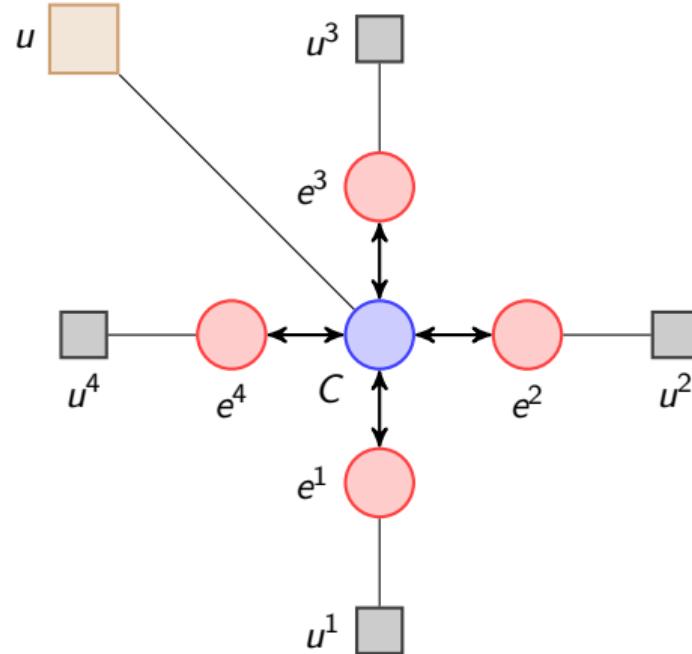

<sup>5</sup> Michael P. Wellman, Eric Sodomka, and Amy Greenwald. "Self-confirming price-prediction strategies for simultaneous one-shot auctions". In: *Games and Economic Behavior* 201 (2017), pp. 339–372.

# Concurrent Negotiations

In ANAC SCML, an agent negotiates with multiple agents simultaneously. Moreover, the agent's utility depends on the outcomes of all the negotiations.

An agent represents a factory, whose production depends on the inputs it acquires from all its trading partners, and so, in turn, does its sales.

# Expected Marginal Utility

An **outcome prediction** is a joint distribution over the outcomes of all (say,  $n$ ) concurrent negotiations: i.e.,  $P(\omega) = P(\omega_1, \dots, \omega_n)$ , where  $\omega_i \in \Omega_i$  and  $\Omega = \prod_{i=1}^n \Omega_i$ .

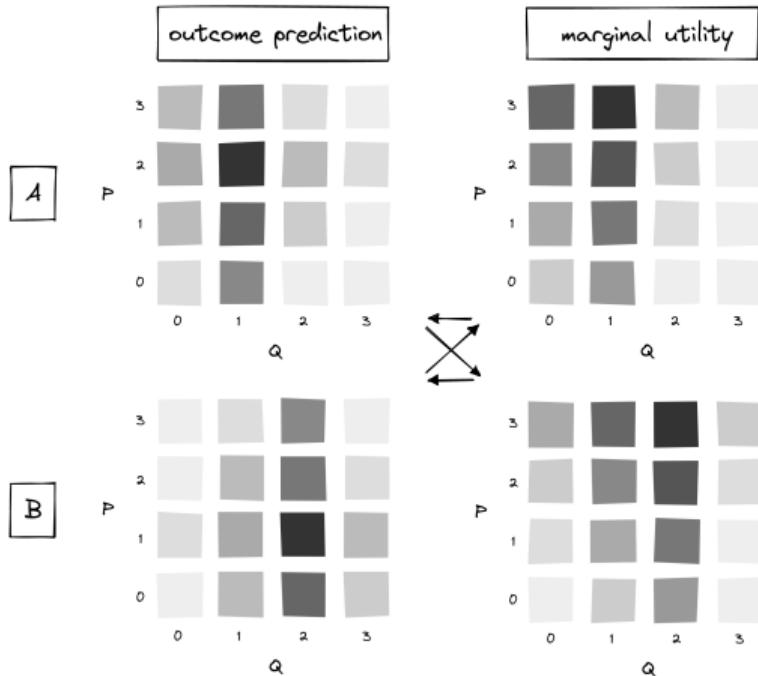

Given an outcome prediction  $P$ , the **expected marginal utility**  $\mu_i$  of outcome  $\omega_i \in \Omega_i$  in negotiation  $i$  is:

$$\mu_i(\omega_i; P) = \mathbb{E}_{\Omega_{\neg i} \sim P_{\neg i}} [u(\{\omega_i\} \cup \Omega_{\neg i}) - u(\Omega_{\neg i})] ,$$

where  $P_{\neg i}$  is the outcome prediction for all negotiations other than  $i$  (i.e.,  $P$  marginalized over  $i$ ).

# SCML OneShot: GodFather Strategy

- We are a seller with three goods to sell
- The arrows indicate dependencies in the expected marginal utility calculations
- Darker squares indicate higher probability predictions and higher marginal utilities
- Since we predict opponent *A* to most likely want 2 goods and *B* to most likely want 1, the highest marginal utility is obtained by contracting to sell 1 to opponent *A* and 2 to opponent *B* (at the highest possible prices)

Joint work with Jackson de Campos, Ben Fiske, and Chris Mascioli

# Outcome Predictions

An outcome prediction is a joint distribution over the outcomes of all concurrent negotiations:  
i.e.,  $P(\omega) = P(\omega_1, \dots, \omega_n)$

- Static model: Depends on factors external to the current negotiation,  
e.g., the state of the world, past negotiations, etc.

$$P(\omega \mid \text{external factors})$$

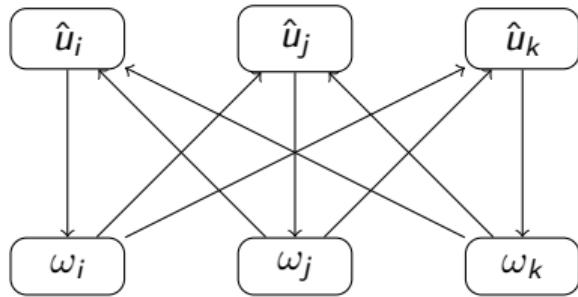

- Dynamic model: Depends on factors both external and internal to the current negotiation,  
i.e., the current negotiation trace so far

$$P(\omega \mid \text{both external and internal factors})$$

- Introspective model: Expected marginal utilities depend on the outcome predictions. Likewise, the outcome predictions depend on the expected marginal utilities (because they affect our behavior).

$$P(\omega \mid \text{both external and internal factors, and expected marginal utilities})$$

# Introspective Equilibrium

An **introspective equilibrium**<sup>5</sup> is a situation in which the outcome predictions are consistent with the marginal utilities, meaning  $P(\omega | \dots)$  and expected marginal utilities  $\mu(\cdot; f) = f$ .

Equivalently, for all negotiations  $x$ ,  $\mu_i(\omega_i; P(\omega | \dots)) = f_i(\omega_i)$ .

<sup>5</sup>Wellman, Sodomka, and Greenwald, "Self-confirming price-prediction strategies for simultaneous one-shot auctions".

# Open Questions

Decoupling negotiations tames the complexity, but is this kosher? How far from optimal is this approach?

How do you build reliable prediction models: static, dynamic, and introspective?

When does simple iteration converge to an introspective equilibrium?

# Automated Negotiation is important

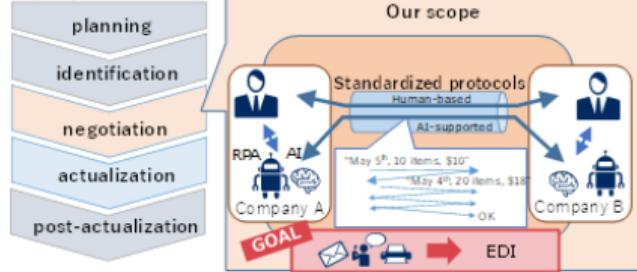

## Why is it hard?

- Mechanism Design Problem:
  - Better than haggling?
- Negotiator Design Problem:
  - Generality × Effectiveness

## Why is it interesting?

- Easy to state yet hard to solve.
- Multiple levels of abstraction and complexity.
- Several concrete open questions.
- Vibrant yet not saturated research space.

Five fundamental activities of a business transaction (ISO/IEC 15944-1)

attribution: UNECE eNegotiation Project

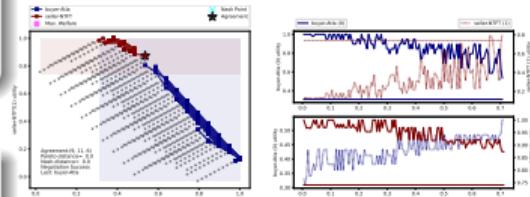

Automated Negotiating Agents Competition: 2010-

# Automated Negotiation Has a Long History

## Nash Bargaining Game (1950)

How to split a pie when you have one offer? Maximize relative surplus product

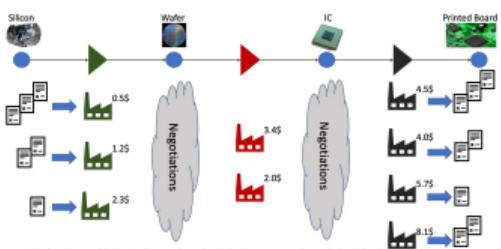

## Robenstien Bargaining Game (197s)

Do we need to negotiate if we know everything? Not really

## ANAC: 2010 and still running

Can we develop effective agents for automated negotiation in almost any domain? Kind of

An example of an SCM world showing four products (circles), three processes (triangles) and few factories. Each process consumes one item of its input and generates one output of its output in one day. Each factory requires a different cost to run its process [shown in its top right]. Factories in the first level have exogenous contracts to buy raw material (silicon) and factories at the last level have exogenous contracts to sell the final product (printed boards). These contracts drive the market.

## SCML 2019 and still running

Can we develop effective agents that orchestrate multiple related negotiations while being embedded in a business like environment? Kind

# We have Nice Platforms?

## Genius<sup>1</sup>

a Java-based negotiation platform to develop general negotiating agents and create negotiation scenarios.

## GENIUS

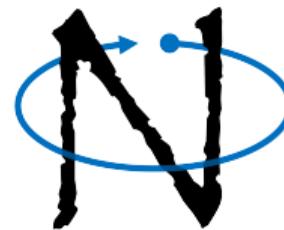

>> General Environment for Negotiation with Intelligent multi-purpose Usage Simulation.

## GeniusWeb

A distributed platform for automated negotiation on the internet

## NegMAS<sup>2</sup>

a Python-based negotiation platform for developing autonomous negotiation agents embedded in simulation environments.

# You know what it takes to build a negotiator

## Offer Policy

What should I offer next?

- Good Heuristics exist
  - Time-based
  - Tit-for-Tat
  - ANAC agents (more than 50)
- Good learners exist but the best ones require unrealistically large amounts of data.

## Acceptance Strategy

When should I accept my partner's offer?

- Several heuristics exist.
- We can learn good acceptance Strategies.
- Still, it may not be a good idea to separate acceptance from offering.

## Opponent Model

# There is too much still to be done

## Strategies with Guarantees

Can we develop strategies that combine the guarantees of classic Game theoretic work with the effectiveness of modern heuristics?

## Concurrent Negotiation

How coordinate behavior in multiple negotiation threads?

## Negotiation under uncertainty

How to behave when I do not know exactly what I want?

## Preference Elicitation

Should I ask? And what exactly should I ask about?
